QuestionAnswer How does the principle of conservation of energy apply to a roller coaster, and what role does potential and kinetic energy play? The conservation of energy principle states that energy cannot be created or destroyed, only transformed. In a roller coaster, as it climbs the initial hill, potential energy increases. As it descends, potential energy converts to kinetic energy, making it move faster. At the bottom, kinetic energy is at its maximum, and at the top of hills, potential energy is at its peak again. Throughout the ride, total mechanical energy remains approximately constant, neglecting friction. Explain how the concept of refraction affects the bending of light when passing from air into water. Refraction occurs because light changes speed when passing from one medium to another. When light enters water from air, it slows down because water is denser. This change in speed causes the light to bend towards the normal line. The amount of bending depends on the refractive indices of the two media, described by Snell's law. Describe how a simple electric circuit works and the role of components like resistors and batteries. A simple electric circuit allows electric current to flow through a closed loop. The battery provides the voltage, pushing electrons around the circuit. Resistors control the current flow by providing resistance, which converts electrical energy into heat or other forms. The flow of electrons (current) is driven by the potential difference supplied by the battery, enabling devices like lights or motors to operate. What factors affect the time period of a pendulum, and how does length influence it? The time period of a pendulum depends primarily on its length and the acceleration due to gravity. The longer the pendulum, the longer the time period. Specifically, the time period is proportional to the square root of its length. Factors like air resistance and amplitude have minimal effects when the amplitude is small. How does the Law of Reflection apply to the way a mirror forms an image? The Law of Reflection states that the angle of incidence equals the angle of reflection, measured relative to the normal line at the point of contact. This principle allows a mirror to produce a virtual image that appears to be behind the surface, as light rays reflect off the mirror and reach our eyes, forming an image that retains the same size and orientation as the object. Explain why objects appear colored under white light and how this relates to absorption and reflection. Objects appear a certain color because they reflect specific wavelengths of light while absorbing others. For example, a red object reflects red wavelengths and absorbs others. Under white light, which contains all colors, only the reflected wavelengths reach our eyes, giving the object its apparent color. Discuss how the principle of moments explains equilibrium in a balanced see-saw. The principle of moments states that for an object to be in equilibrium, the sum of clockwise moments must equal the sum of anticlockwise moments about a pivot point. On a see-saw, this means that the weight multiplied by its distance from the pivot on one side must balance the same on the other side. This balance keeps the see-saw level. How does the concept of pressure relate to fluids and why does water exert pressure at depth? Pressure in a fluid at a given depth depends on the weight of the fluid above that point. As depth increases, the pressure increases because of the greater amount of fluid exerting force downward. This is described by the equation P = ?gh, where ? is density, g is gravity, and h is depth. Describe how a transformer works and its application in electrical power distribution. A transformer works on the principle of electromagnetic induction, using two coils of wire (primary and secondary) wrapped around a magnetic core. When an alternating current flows through the primary coil, it creates a changing magnetic field, inducing a voltage in the secondary coil. Transformers can

step up or step down voltage levels, making electrical power transmission more efficient over long distances. Explain what causes diffraction of waves and give an example involving light or sound. Diffraction occurs when waves encounter an obstacle or opening comparable in size to their wavelength, causing them to spread out or bend around the obstacle. For example, light passing through a narrow slit produces a diffraction pattern of bright and dark fringes, while sound waves diffracting around corners allow us to hear around obstacles.
